

Jones Billing Widget Review

A. Issues Found

1. Security / Completeness: Missing CVV Field

The form displays the card number, cardholder details, and expiration date, but no visible CVV field.

Issue: Most payment forms include a CVV field as part of card verification.

Impact: Users may expect to see a CVV field, and its absence may cause confusion or reduce trust.

2. Usability: Credit Card Number Instructions

The Card Number field includes the instruction "No dashes or spaces".

Issue: Most users naturally enter credit card numbers with spaces.

Suggested Improvement: Allow spaces and format the number automatically.

3. Usability: Payment Amount Visibility

The payment amount is displayed as "30.00".

Issue: The currency is not shown.

Impact: Users cannot tell whether the amount is USD, EUR, GBP, ILS, or another currency.

4. Usability: Payment Context

Only the payment amount is displayed.

Issue: The user cannot see what the payment is for.

Impact: Users may hesitate to continue without understanding the purpose of the charge.

5. Usability: Missing Placeholders or Examples

Most fields do not provide example values or input guidance.

Issue: There are no examples showing the expected format for fields such as card number, address, or postal code.

Impact: This may increase input errors and slow down form completion.

6. Usability / Internationalization: Address Section and Postal Code

Two address fields are displayed under "Credit Card Billing Street Address".

Issue: The purpose of the second field is unclear.

The Postal Code field includes the instruction "no dashes", although some international postal codes contain letters and spaces.

Impact: Users may enter incorrect information or be unsure how to complete the field.

7. Accessibility: Required Fields

Required fields are marked only with a red asterisk (*).

Issue: Users with visual impairments or color blindness may have difficulty identifying required fields.

8. Usability / Internationalization: Middle Initial (MI) Field

The form includes a field labeled "MI".

Issue: The abbreviation may not be understood by international users and is not commonly used in many countries.

9. Usability: Expiration Date

The expiration date is entered using two dropdown lists.

Issue: Most users are familiar with the MM/YY format shown on physical cards.

10. Security / Trust: Trust Indicators

No security badges, payment provider logos, or security related messaging are displayed.

Impact: Users may feel less confident entering payment information.

11. Performance

No clear performance issue can be confirmed from the static UI mock-up alone.

Performance would need to be checked on the running product.

B. Sample Test Cases

Test Case 1: Successful Payment Submission

Preconditions: Billing form is displayed.

Steps:

1. Select a credit card type.
2. Fill all required fields with valid data.
3. Click Continue.

Expected Result:

The form should be submitted successfully and the user should continue to the next step in the payment flow.

Actual Result: N/A

Status: Not Executed

Test Case 2: Verify CVV Field Presence

Preconditions: Billing form is displayed.

Steps:

1. Review the payment section.
2. Check the card details area.

Expected Result:

A CVV or Security Code field should be displayed as part of the payment information.

Actual Result:

No CVV field is displayed in the provided mock-up.

Status: Failed

Test Case 3: Credit Card Number Input With Spaces

Preconditions: Billing form is displayed.

Steps:

1. Enter a valid card number with spaces.
2. Complete the rest of the form.
3. Click Continue.

Expected Result:

The system should accept the card number and automatically remove or format spaces.

Actual Result: N/A

Status: Not Executed

C. Product Solution for the Most Severe Issue

Most Severe Issue

The payment form does not display a visible CVV field.

Suggested Product Solution

Add a CVV field next to the card number and expiration date fields.

1. A clear label such as "CVV" or "Security Code"
2. A short explanation showing where the code can be found on the card
3. Validation for the expected length, usually 3 to 4 digits
4. Masking of the entered value
5. A clear error message when the value is missing or invalid

This would make the payment form feel more complete and align it with common payment form expectations.
